

- (10%) A local health center noted that in a sample of 400 patients 80 were referred to them by the local hospital:
  - Provide a 95% confidence interval for all the patients who are referred to the health center by the hospital. (5%)
  - What sample size would be required to estimate the error of 0.08 or less at 95% confidence? (5%)
- (10%) The results of a recent poll on the preference of voters regarding presidential candidates are shown below:

Candidate	Voters Surveyed	Voters Favoring This Candidate
A	400	192
B	450	225

At 95% confidence, test to determine whether or not there is a significant difference between the preferences for the two candidates.

- (15%) The number of emergency calls per day at a hospital over a period of 120 days are shown below:

Number of Emergency Calls (X)	Observed Frequency (f)
0	9
1	12
2	30
3	27
4	22
5	13
6	7
Total	120

Use  $\alpha = 0.05$  and test to see if the above data have a Poisson distribution.

- (15%) An automobile dealer wants to see if there is a relationship between monthly sales and the interest rate. A random sample of 4 months was taken. The results of the sample are presented below. The estimated least square regression equation is  $\hat{Y} = 75.06 - 6.2536 X$

Y Monthly Sales	X Interest Rate (%)
22	9.2
20	7.6
10	10.4
45	5.3

- Obtain a measure of how well the estimated regression line fits the data. (5%)
- You want to test to see if there is a significant relationship between the interest rate and monthly sales at the 1% level of significance. State the null and alternative hypotheses. (5%)
- Construct a 99% confidence interval for the average monthly sales for all months with a 10% interest rate. (5%)

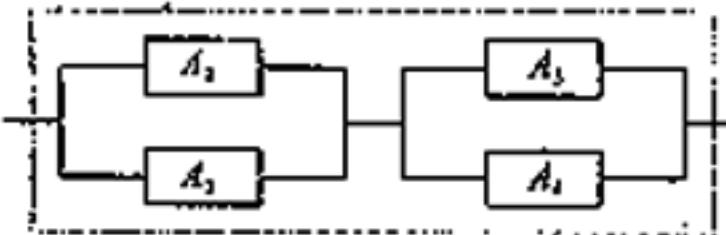

5. (15%) To enter a one-question contest, you have a choice of forming a 2-person team or a 4-person team. The enrollment fee is 500 dollars per person and the winning prize is 4000 dollars. The game rule is that the team wins if at least one person in the team gets the right answer. It is assumed that everybody in the team is equally intelligent and can get the right answer with probability  $p$  independently of each other.
- Suppose you form a 2-person team to enter the contest. For what value of  $p$  can you have non-negative expected return? (5%)
  - For what value of  $p$  is a 4-person team no different from a 2-person team in terms of the expected return? (7%)
  - Would a 4-person team always be a better choice than a 2-person team? Please explain. (3%)

6. (10%) The following estimated regression equation involving three independent variables has been developed:

$$\begin{aligned}\hat{y} &= b_0 + b_1 x_1 + b_2 x_2 + b_3 x_3 \\ &\approx 19.1 + 8.5 x_1 + 18.0 x_2 - 4.5 x_3\end{aligned}$$

where the estimates of the standard deviations of  $b_1$ ,  $b_2$  and  $b_3$  are  $s_{b_1} = 2.4$ ,  $s_{b_2} = 9.5$ , and  $s_{b_3} = 0.9$  respectively. There were 15 observations in the study. Would you recommend dropping any of the independent variables from the model? (Using  $\alpha=0.05$ )

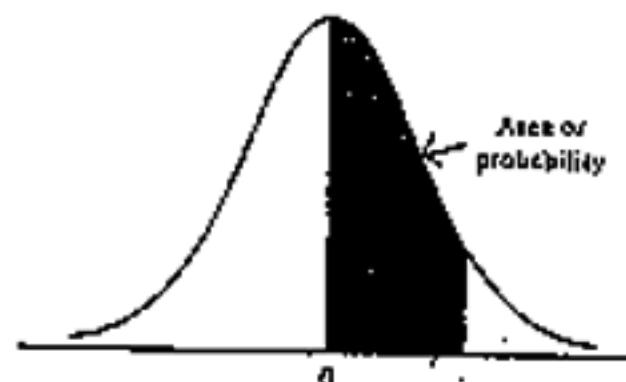

7. (15%) A system consists of four components  $A_1$ ,  $A_2$ ,  $A_3$  and  $A_4$ , as shown in the following diagram. The system will function if at least one of  $A_1$  and  $A_2$  functions and at least one of  $A_3$  and  $A_4$  functions. Suppose each component would fail with probability  $(1-p)$  independently of each other.

- What is the probability that the system would function? (5%)
  - Suppose now that each component  $A_i$  has a resistance  $R_i$ ,  $R_i = (1/p) \Omega$  if  $A_i$  is functioning;  $\infty$  if  $A_i$  is not functioning. If two components  $A_i$  and  $A_j$  are in series, the equivalent resistance for  $A_i$  and  $A_j$  would be  $(R_i + R_j)$ . If  $A_i$  and  $A_j$  are in parallel, on the other hand, the equivalent resistance for  $A_i$  and  $A_j$  would be  $(R_i R_j) / (R_i + R_j)$ . What is the probability the system has the resistance less than  $0.7\Omega$  given that the system is functioning? (10%)
8. (10%) You are about to stack 150 coins on a smooth surface. There will be a shaking test when you stack 50, 100 and 150 coins respectively. Assume the coins would collapse only in these three shaking tests (not in your stacking process). It takes you 10 minutes to stack 50 coins that would collapse with probability  $p_1$  in the first shaking test. It takes you 20 minutes more, if passing the first test, to stack another 50 coins and the total 100 coins would collapse with probability  $p_2$  in the second shaking test. Finally, it takes you 30 minutes more, if passing the second test, to stack another 50 coins and the total 150 coins would collapse with probability  $p_3$  in the final test. If the coins collapse in one of the shaking tests, you repeat the stacking process from the beginning. Assuming these shaking tests take no time, what would be the expected length of time until you can successfully stack 150 coins?

附錄 I

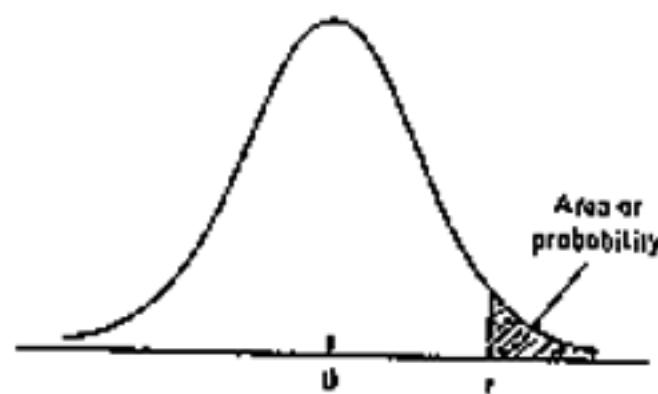

TABLE  
Standard Normal  
Distribution

Entries in the table give the area under the curve between the mean and  $\pm z$  standard deviations above the mean. For example, for  $\pm 1.25$  the area under the curve between the mean and  $\pm z$  is .3944.

## 附表2

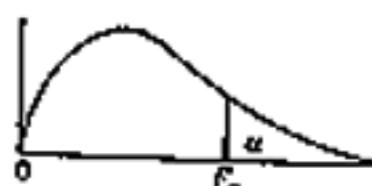

TABLE  
*t* Distribution

Entries in the table give *t* values for an area or probability in the upper tail of the *t* distribution.  
For example, with 10 degrees of freedom and a .05 area in the upper tail, *t*<sub>0.05</sub> = 1.812.

Degrees of Freedom	Area in Upper Tail				
	.10	.05	.025	.01	.005
1	3.078	6.214	13.706	31.821	63.637
